

Where to find the beam splitter port

Article Overview

A beam splitter typically has two input ports and two output ports, which can be identified by the direction of incident light and the paths of transmitted and reflected beams.

Identifying Input and Output Ports

Cube beam splitters usually have a cube shape with two faces designated as input ports and the other two as output ports. For a symmetric 50/50 cube beam splitter, the input ports are often located on the bottom and left sides, while the output ports are on the top and right sides. Light entering an input port is partially transmitted and partially reflected, emerging from the corresponding output ports. Plate beam splitters are flat and thin, with one side coated to partially reflect light. The input port is the side where the incident beam strikes, and the output ports are the transmitted beam (continuing straight) and the reflected beam (deflected at an angle, usually 90° from the incident path).

Practical Steps to Locate Ports

- **Visual Inspection:** Look for the coated surface (for plate splitters) or the interface between prisms (for cube splitters). The coated or interface side usually faces the incoming light.
- **Trace the Beam Path:** Shine a low-power laser or light source at one face. The transmitted beam continues straight, while the reflected beam exits at an angle. These define the output ports.
- **Labeling Convention:** In experiments, ports are often labeled as 1 and 2 for inputs, and 3 and 4 for outputs. For example, if a photon enters input port 1, it can exit thr...
